

PROPERTY MANAGEMENT SYSTEM

IMPLEMENTATION LOGIC:

We have implemented property management system using cpp language with oops concepts to help the people who wanted to sell or buy the properties easily. In this project we used database MYSQL to store the data and oops concepts like Exception Handling, Inheritance.

Firstly, we have connected DEV-C++ to MYSQL database and created four tables in database called admin, customer, booked and property. In which we will store the admin details, customer details, the booked details, and all property details respectively. Coming to the code implementation firstly, we have given four options they are Sign Up, Sign In, Admin Sign-In and Exit.

➤ Sign Up:

If the user is new then he has to select Sign Up option then, it will ask to enter their details such as Name, Phone number etc. In Phone Number We have used exception handling concept that the user has to enter only 10 numbers if he entered more than that it will throw an error .After entering their details it will ask the

user if he want to sell or buy the property(Y/N)? if he entered Y then he will sign up as admin and it will ask him the username and password for security purpose as it will check the entered data with the existing data in the database with the help of checkACredentials Function which we have written. This entered data is directly save to the property table in database. If he entered 'N' he will sign up as Customer.

➤ Sign In:

If the user has an account already then he can select sign in option and he can entered his user name and password to signin then it will display four options

1. View Property list.
2. Search Property List.
3. Book Property.
4. Main menu.

If he selected 1 then it will display all the property details from the property table in our database here we have created one class called Sign in and inherited from the other two classes called Property and CheckCCredentials which we used to enter the property details and to check the customer details respectively.If he enter 2 then it will search the property by two ways that is by location and by property Id . If he enter 3 it will book the data whatever he want and that data will add to the booked table. Here in class signin we have created 3 member

functions called viewprop(),searchprop(),bookprop() to implement the above idea.

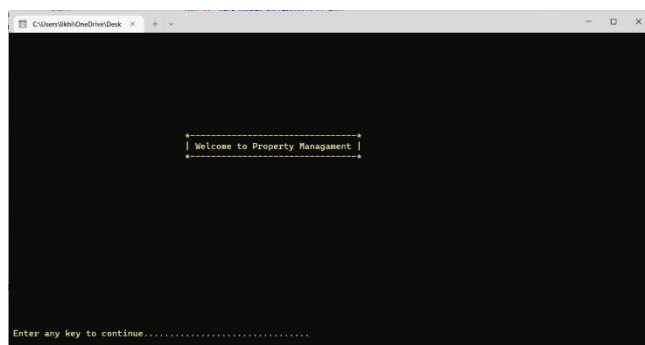

➤ Admin Sign-In:

If the user selected admin sign-in then it will ask to enter the user name and password it will check the database with the help of CreckACredential Function. It will ask 6 options they are

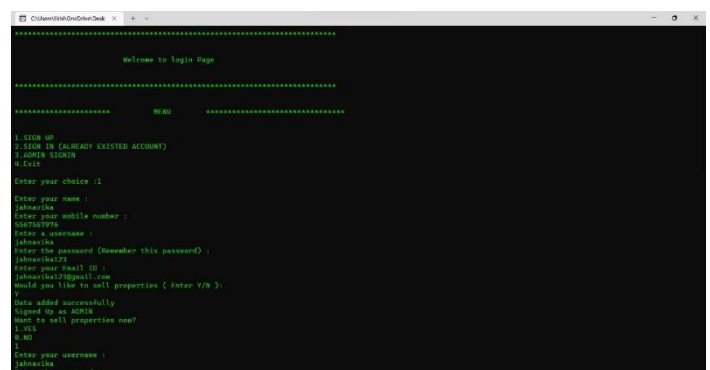

1. Add Details
2. View list
3. View all Bookings
4. Delete Record
5. Main Menu
6. Exit

Here, we have created a _Sign-in class which is inherited from the property class with public functions checkAdmin, ViewAprop, bookedaprop ,deleteAprop to implement above requirments.

Result:

Individual Contribution:

Property Management system:

K Sai Likhitha (S20210020289)

Classes-Sign Up , CheckCCredential, Sign-in.

Functions-getsignupdata ,checkCdata ,viewprop ,searchprop ,locationsearch ,pidsearch ,bookprop.

V Jahnika Reddy(S20210020330)

Classes-CheckACredentials, Property a_signin database_connection.

Functions- checkAdata, getpropertydata ,checkadmin ,viewAprop,bookedAprop,deleteAprop

Conclusion:

So ,From this management system we have made the process of selling and buying the properties friendly to users with multiple admins accessing the bookings of the properties.

EVENT MANAGEMENT SYSTEM

IMPLEMENTATION LOGIC:

We have implemented event management system using c++ language with oops concepts to help the people who wanted to organize an event or book an event easily. In this project we used database MYSQL to store the data and oops concepts like Exception Handling, Inheritance.

Firstly, we have connected DEV-C++ to MYSQL database and created four tables in database called organiser, customer, information and signup. In which we will store the admin details, customer details, the booked details, and all booked event details respectively.

Coming to the code implementation firstly, we have given three options they are Sign Up, Sign In and Exit.

```
*-----*
| Welcome to login page |
*-----*

*-----*
| 1. SIGN UP(NEW ACCOUNT)
| 2. SIGN IN(ALREADY EXISTING ACCOUNT)
| 3. EXIT
|
*-----*
```

➤ Sign Up:

If the user is new then he has to select Sign Up option then, it will ask to enter their basic details such as Name, Phone number, emailid etc. After entering their details it will ask the user if he want to organise an event or book an event(1/2)? if he entered 1 then he will sign up as organiser and it will ask him the username and password for security purpose as it will check the entered data with the existing data in the database with the help of organiser database table we have organiser. For organiser we are taking some basic information for the data and security issues. This entered data is directly save to the organiser table in database. If he entered '2' he will sign up as Customer. For customer it will ask basic information like email address to create an account in customer database table.

➤ **Sign In:**

If the user has an account already he have to say whether he is a customer or organiser (1/2)?

If the user enter 1->customer he has to enter username and password ,then here we were using exception handling to the password if he press wrong password he was asked to check again ,only two chances we are allocated after that also if there is an wrong password it will again enter to the login page. This whole operation is in void checkcustomer() .

After customer checking we are providing two options to book an event and display their booked data.

For booking we created a function bookdata() inside the class admincustomerdata .

If the user enter 2->organiser he has to enter username and password ,then here we were using exception handling to the password if he press wrong password he was asked to check again ,only two chances we are allocated after that also if there is an wrong password it will again enter to the login page. This whole operation is in void checkorganise() .

After organiser checking we are providing two options to add a new event ,display their booked data .

For adding new event we created a function addnewdata() inside the class admincustomerdata .

For displaying the respective organiser booking data we created displayorganiserdata() in class signin.

HIERARCHICAL INHERITANCE:

BASE CLASS : signup

DERIVED CLASS: admin class and customer class

```
//Base class SIGN UP and derived class is customer class

class customer : public signup{
private:
    //total information display and wt he wat to bbok in event
